## IMAGE FORMING APPARATUS

### FIELD OF THE INVENTION AND RELATED ART

The present invention relates to a heating apparatus, in particular, of an electromagnetic (magnetic) induction type, preferably usable as an image fixing apparatus for fixing an unfixed image, with the use of the combination of heat and pressure, in an image data recording apparatus (image forming apparatus) such as a copying machine, a printer, a facsimileing machine, etc.

The present invention will be described with reference to an image heating apparatus mountable in an image forming apparatus, for example, an electrophotographic copying machine, a printer, a facsimileing machine, etc.

The image heating apparatus in an image forming apparatus is an apparatus for thermally and permanently fixing an unfixed toner image to the surface of recording medium. Here, an unfixed toner image means an image directly or indirectly (transfer) formed on the surface of recording medium as an object to be heated, with the use of toner (developing agent) formed of thermally meltable resin or the like, by an optional image forming processing means, for example, an electrophotographic or electrostatic recording process, in the image formation station of an image

forming apparatus.

There are various thermal image fixing apparatuses in accordance with the prior art, for example, a fixing apparatus employing a single or 5 plurality of rollers containing a heat source, a fixing apparatus employing an induction heating system, etc.

Generally, a heat roller type fixing apparatus comprises a pair of rotational rollers, more 10 specifically, a fixation roller (heat roller), in which a heat source such as a halogen lamp is disposed, and the temperature of which is kept at a predetermined level, and a pressure roller. In operation, recording medium bearing an unfixed toner 15 image is introduced into, and conveyed through, the contact nip (fixation nip) between the two rollers, so that the unfixed image on the recording medium is thermally fixed to the surface of the recording medium.

20 However, the amount of electrical power which this type of a thermal fixing apparatus requires for heating is rather large, because its fixation roller is rather large in thermal capacity. Therefore, this type of a thermal fixing apparatus is rather long in 25 wait time (length of time it takes for apparatus to become ready for print output after apparatus is turned on), which is problematic. Further, in order

to raise the temperature in the fixation nip formed by a fixation roller, which is rather large in thermal capacity, in a limited length of time, a large amount of electric power is necessary, which is also

5 problematic.

As one of the measures commonly practiced to counter these problems is to reduce a fixation roller in thermal capacity by reducing the fixation roller in wall thickness. This measure, however, is problematic

10 for the following reason. That is, if a fixation roller is reduced in wall thickness in order to reduce its thermal capacity, it is reduced in the thermal conduction in terms of its length direction (lengthwise direction of fixation nip). Therefore, as

15 narrow recording medium is passed through the fixing apparatus, the portions of the roller(s) outside the recording medium track (path) excessively rises in temperature, reducing thereby the service life of the fixing roller and/or pressure roller.

20 One of the countermeasures to this problem is to employ halogen lamps as the heat source for a fixing apparatus. More specifically, a fixing apparatus is provided with a plurality of halogen lamps, which are different in the range, in terms of

25 the lengthwise direction, across which light is emitted, and the timing with which they are turned on is tied to the width of the recording medium. Thus,

the excessive temperature increase of the portions of the fixation nip, outside the recording medium track, is prevented by controlling the timing with which each of the plurality of halogen lamps is turned on. This  
5 measure, however, requires a measure for dealing with the high frequency flickering of the halogen lamps, because this measure requires the plurality of halogen lamps to be turned on and off to control the heat distribution in the fixation nip. One of the  
10 proposals for eliminating this flickering from a thermal fixing apparatus is to employ one of the induction heating systems, which has begun attracting attention in recent years. Next, a typical induction heating system will be described.

15 An induction heating system employs an induction heater as a heating member. In operation, an induction heating member is subjected to the magnetic field generated by a magnetic field generating means, inducing thereby eddy current in the  
20 induction heating member, which in turn generates the Joule heat in the induction heating member. This heat is applied to the recording medium, as an object to be heated, to fix the unfixed toner image on the recording medium to the surface of the recording  
25 medium.

Patent Document 1, given below, discloses a heat roller type thermal fixing apparatus, in

accordance with the prior art, employing a ferromagnetic fixation roller in which heat can be generated by induction. With the employment of such a heat roller, heat can be generated near the fixation  
5 nip. Therefore, the heat roller type thermal fixing apparatus disclosed in Patent Document 1 is superior in thermal efficiency to a fixing apparatus employing a heat roller containing halogen lamps as heat sources.

10 However, the fixation roller which the fixing apparatus disclosed in Patent Document 1 employs the fixation roller, which is relatively large in thermal capacity. Therefore it is problematic in that it requires a relatively large amount of electric power  
15 in order to raise the temperature in the fixing nip within a limited length of time. One of the solutions to this problem is to reduce the fixation roller in thermal capacity, and one of the methods to reduce the fixation roller in thermal capacity is to reduce the  
20 fixation roller in wall thickness.

Patent Document 2 discloses a fixing apparatus employing an induction heating system, different from the one disclosed in Patent Document 1, which comprises a fixing member in the form of film  
25 which is much smaller in thermal capacity than a fixation roller.

This fixing apparatus also has a problem in

that even if a fixing member in the form of film, which is smaller in thermal capacity than a fixation roller, is employed, the portions of the fixation nip outside the recording medium track excessively

5 increase in temperature, reducing thereby the service life of the fixation film and/or pressure roller.

Patent Documents 3 and 4 disclose a heating apparatus characterized in that it comprises a magnetic flux adjusting means capable of changing the 10 distribution of the effective magnetic flux generated by the magnetic flux generating means, in terms of the widthwise direction of the fixation member (film). This type of induction heating system indicates one of the directions of the solution for eliminating the 15 problem that the portions of the fixation nip outside the recording medium track excessively increase in temperature.

The fixing apparatuses in the aforementioned documents 3 and 4 disclose fixing apparatuses 20 comprising a heating member, in the form of a piece of film, which generates heat by induction. According to these documents, it seems that using a cylindrical inductive heating member as a fixation roller is effective as a countermeasure to the excessive 25 temperature increase across the portions of the fixation nip outside the recording medium track.

As the method, other than the aforementioned

ones, for solving the problem of the excessive temperature increases across the portions of the fixation nip outside the recording medium track, there  
is a method in which fixation speed (throughput) is  
5 reduced when a recording medium of smaller (narrower) recording medium is passed. In this case, the reduction in fixation speed provides a longer time for the heat in the lengthwise end portions (portions outside recording medium track) of a fixation roller  
10 to conduct into the recording medium track portion of the fixation roller. This method, however, reduces the productivity of an image forming apparatus.

Publication 5-9027

15 Document 2: Japanese Laid-open Patent Application  
4-166966

Document 3: Japanese Laid-open Patent Application  
9-171889

20 Document 4: Japanese Laid-open Patent Application  
10-74009.

As will be evident from the above descriptions, image fixing thermal apparatuses employing one of the well-known heating systems, more specifically, the heat roller type heating system and  
25 electromagnetic induction heating system, in accordance with the prior art, generally have the following problems.

A fixing apparatus, in accordance with the prior art, employing a single or plurality of rollers in which a single or plurality of halogen lamps are disposed as heat sources suffers from the following 5 problems.

The lines feeding the halogen lamps with electrical power extend outward from both lengthwise ends of a fixation roller. Thus, in order to replace the fixation roller, it is necessary to uncouple two 10 electrical joints at the lengthwise ends of the fixation roller, one for one. The joints also have to be uncoupled in order to replace the halogen lamps. Thus, the operation for replacing the fixation roller and/or halogen lamps cannot be completed from one side 15 of the fixing roller.

Further, when assembling a fixing apparatus, the lines for feeding the halogen lamps with electrical power have to be inserted into the fixation roller, providing thereby the opportunity for the 20 power feeding lines to become scratched and/or bent by coming into contact with the internal surface of the fixation roller.

These problems reduce the efficiency with which a fixing apparatus is assembled, as well as the 25 efficiency with which a fixing apparatus is serviced, for example, when the structural components are replaced.

The fixing apparatuses, disclosed in the Patent Documents 3 and 4, which employ one of the induction heating systems in accordance with the prior art, as a countermeasure to the excessive temperature increase outside the recording medium track, also suffer from the problems similar to the above described ones.

In the case of a fixing apparatus employing an induction heating system in accordance with the prior art, the lines for feeding an exciter coil can be disposed at one of the lengthwise ends of the fixation roller. However, the relationship between the lines for feeding a magnetic flux adjusting means and the lines for feeding an excitation coil have not been shown in practical terms.

SUMMARY OF THE INVENTION

The present invention was made in consideration of the above described problematic points, and its primary object is to provide an electromagnetic induction type heating apparatus which comprises a magnetic flux adjusting means for dealing with the problem of excessive temperature increase outside the recording medium track, and which is superior to a heating apparatus in accordance with the prior art, in terms of the efficiency with which a heating apparatus can be assembled, the efficiency

with which the structural components of a heating apparatus can be replaced, the space dedicated to the means for driving the magnetic flux adjusting means, the space dedicated to the excitation coil, and the 5 interference between the means for driving the magnetic flux adjusting means and excitation coil.

An image forming apparatus for accomplishing the above objects comprising the following:

These and other objects, features, and 10 advantages of the present invention will become more apparent upon consideration of the following description of the preferred embodiments of the present invention, taken in conjunction with the accompanying drawings.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5    Embodiment 1

Figures 1 - 4 show an example of the electromagnetic induction type thermal fixing apparatus, as a heating apparatus, in accordance with the present invention.

10       Figure 1 is a schematic sectional view of the fixing apparatus in this embodiment, parallel to the lengthwise direction (axial direction) of the fixation roller, showing the general structure thereof. Figure 2 is a schematic sectional view of the fixing

15       apparatus in the first embodiment of the present invention, parallel to the diameter direction of the fixation roller, showing the general structure thereof. Figure 3 is an exploded view of the magnetic flux adjustable heating assembly of the fixing

20       apparatus in the first embodiment, showing the structures of the magnetic flux blocking member and magnetic flux generating means.

The fixing apparatus in this embodiment is presented as an example of a fixing apparatus in order  
25       to describe the relationship, between the magnetic flux blocking member gear, and fixation roller, for improving a fixing apparatus in terms of ease of

5 maintenance, more specifically, the efficiency with which the components of the magnetic flux adjustable heating assembly can be serviced or replaced, as well as the efficiency with which a fixing apparatus can be  
10 assembled. The magnetic flux blocking member gear is a rotationally drivable member for driving the magnetic flux blocking member, and the fixation roller is an inductive heat generating member.

15 The fixing apparatus in this embodiment essentially comprises: a magnetic flux adjustable heating assembly 1, a fixation roller 7 as an inductive heating member, and a pressure roller 8.

20 The magnetic flux adjustable heating assembly 1 comprises: an excitation coil 5 (which hereinafter will be referred to simply as "coil") as a magnetic flux generating means, a magnetic core 6 (which hereinafter will be referred to as "core"), and a holder (holding member) 2 for holding the coil 5 and core 6, and a magnetic flux blocking member 3, as a magnetic flux adjusting means, having an arcuate cross section, rotatable in the counterclockwise or clockwise direction indicated by arrow marks a or b, respectively, about the lengthwise end portions of the holder 2.

25 The magnetic flux generating means comprises the coil 5, and the core 6 having a T-shaped cross section, disposed within the hollow of the fixation

roller 7. The coil 5 and core 6 are held by the holder 2, and are covered with a holder cover 19.

The coil 5 is roughly elliptic (looking like a canoe positioned in parallel to the axial direction 5 of the fixation roller 7), being elongated in the lengthwise direction of the fixation roller 7. It is disposed in the holder 2, in parallel to the internal surface of the fixation roller 7. The core 6 comprises a primary portion 6a (perpendicular portion) 10 around which the coil 5 is wound, and the secondary portion 6b (horizontal portion) located above the primary portion 6a.

The coil 5 must be capable of generating alternating magnetic flux by an amount large enough to generate a sufficient amount of heat. In order for the coil 5 to generate a sufficient amount of alternating magnetic flux, the coil 5 must be high in inductance. The wire of the coil 5 is Litz wire, that is, a wire composed of roughly 80 - 160 strands of electrically insulated fine wires, the diameters of which are in the range of 0.1 - 0.3 mm, and which are bundled together. In the case of the coil 5, the Litz wire is wound 6 - 12 times around the primary core 6a. To the coil 5, an unshown excitation circuit is ... 15 connected so that alternating current can be supplied to the coil 5 through the excitation circuit. 20

As the material for the core 6, such

substances as ferrite and Permalloy that are high in permeability and low in residual flux density are desired. However, the choice does not need to be limited to these substances as long as magnetic flux 5 can be generated. Further, the shape and material for the core 6 do not need to be limited to the above described ones. For example, the primary and secondary portions 6a and 6b of the core 6 may be integrally formed as a single-piece core 6, and such a 10 construction can provide the same effects as the effects of the present invention which will be described next.

As the material for the cylindrical fixation roller 7 as an inductive heat generating member, such 15 metals as iron, nickel, and cobalt that are ferromagnetic are desired, because the usage of ferromagnetic metal (metal higher in permeability) makes it possible to confine the magnetic flux generated by the magnetic flux generating means 20 (combination of coil 5 and core 6) in the core 6, in other words, to make the core 6 higher in magnetic flux density. Therefore, eddy current is more efficiently induced at the surface of the 25 ferromagnetic core (and therefore, in the surface portion of fixation roller 7), and therefore, heat is generated in the surface portion of the fixation roller 7 by a greater amount.

In order to optimize by reducing the thermal capacity of the fixation roller 7, the wall thickness of the fixation roller 7 is desired to be roughly in the range of 0.3 - 2 mm. The outer most layer of the  
5 fixation roller 7 is an unshown toner releasing layer, which generally is 10 - 50  $\mu$ m thick film of PTFE, or PFA. The fixation roller 7 may be provided with a rubber layer, which is placed on the inward side of the toner releasing layer, in terms of the radius  
10 direction of the fixation roller 7.

The fixation roller 7 is provided with a fixation roller gear 18 attached to one of the lengthwise ends of the fixation roller 7. This gear is rotated by an unshown motor.

15 The pressure roller 8 comprises: a metallic core formed of iron; a silicone rubber layer formed on the peripheral surface of the metallic core; and a toner releasing layer formed on the peripheral surface of the silicon rubber layer. In other words,  
20 structurally, the pressure roller 8 is similar to the fixation roller 7.

The magnetic flux adjusting means of the fixing apparatus in this embodiment, extending in the lengthwise ends of the fixation roller, essentially  
25 comprises a magnetic flux blocking member 3, a holder 2, a magnetic flux blocking member gear 11, and a bushing 14. Among these structural components, the

holder 2 and magnetic flux blocking member 3 are disposed within the hollow of the fixation roller 7.

The fixing apparatus in this embodiment is structured so that the magnetic flux blocking member 3 5 is rotated about the lengthwise end shafts of the holder 2, by which the holder which holds the coil 5 and core 6, is supported.

The lengthwise end portions of the holder 2 are shaped like an axle so that the magnetic flux 10 blocking member 3 can be rotationally supported by the holder 2. In other words, not only does the holder 2 support the coil 5 and core 6, but also rotationally supports the magnetic flux blocking member 3.

The shaft 2a by which the holder 2 is 15 supported on one side, is provided with a magnetic flux blocking member gear 11 for rotating the magnetic flux blocking member 3, whereas the shaft 2b by which the holder 2 is supported on the other side, is provided with the bushing 14 for making it easier for 20 the magnetic flux blocking member 3 to slide. The holder support shafts 2a and 2b are provided with stopper rings 12 and 16, respectively, being thereby controlled in their movement in the thrust direction.

The holder 2 is formed of such a substance 25 that is nonmagnetic, electrically insulating, and higher in heat resistance. For example, the holder 2 is formed of the combination of PPS resin and glass

fiber added thereto, which has both heat resistance and mechanical strength, and obviously is nonmagnetic. If the holder 2 is formed of a magnetic substance, heat is generated in the holder 2 by electromagnetic induction, reducing thereby the efficiency with which heat is generated in the fixation roller by the magnetic flux generated by the coil 5.

As the substances suitable as the primary material for the holder 2, there are PPS resin, PEEK resin, polyimide resin, polyamide resin, polyamide-imide resin, ceramics, liquid crystal polymer, fluorinated resin, or the like.

The substances suitable as the material for the bushing 14 and magnetic flux blocking member gear 11 are basically the same as those for the holder 2; it is desired that one of the more slippery substances among the above listed resinous substances is chosen, for example, polyamide-imide resin, PFA resin, and PEEK resin.

The magnetic flux blocking member 3 is formed of such a substance that is nonmagnetic and is a good conductor of electricity. Forming the magnetic flux blocking member 3 of a nonmagnetic material is effective to block magnetic flux, and forming the magnetic flux blocking member 3 of a good conductor of electricity is effective to minimize the amount of the heat generated in the magnetic flux blocking member 3.

itself by electromagnetic induction. In this embodiment, aluminum alloy is used as the material for the magnetic flux blocking member 3. However, the copper alloy, magnesium alloy, silver alloy, or the like may be used as the material for the magnetic flux blocking member 3.

The thickness of the magnetic flux blocking member has only to be roughly in the range of 0.3 - 1.0 mm. If it is no more than a value in this range, heat is generated in the magnetic flux blocking member 3 itself by electromagnetic induction; besides, the magnetic flux blocking member 3 will be insufficient in mechanical strength. On the other hand, if it is no less than a value in this range, the magnetic flux blocking member 3 will be large enough in thermal capacity to rob the fixation roller of a substantial amount of heat as heat is generated in the fixation roller, increasing thereby the aforementioned wait time.

Referring to Figure 3, the magnetic flux blocking member 3 comprises a pair of magnetic flux blocking portions, which constitute the lengthwise end portions of the magnetic flux blocking member 3. Each magnetic flux blocking portion comprises fixation roller shielding portions 3e (3f) and 3g (3h), which are inside the track of the recording medium with a width A, and which correspond in position to the

portions of the fixation roller (fixation nip) outside the track of the recording medium with a width B, and the track of the recording medium with a width C, respectively, creating a step between the fixation 5 roller shielding portions 3e 3(f) and 3g (3h).

In other words, the magnetic flux blocking member 3 in this embodiment is provided with the pair of fixation roller shielding portions 3e and 3f, and the pair of fixation roller shielding portions 3g and 10 3h, having a step between the shielding portions 3e 3(f) and 3g (3h).

On the holder shaft 2a side, the cylindrical portion 11b of the magnetic flux blocking member gear 11 fits in the hole of the C-shaped end portion of the 15 magnetic flux blocking member 3; the projection 11a of the cylindrical portion 11b of the magnetic flux blocking member gear 11 fits into the U-shaped notch 3a of the C-shaped end portion of the magnetic flux blocking member 3. Therefore, as the magnetic flux blocking member gear 11 is rotated, the magnetic flux blocking member 3 is rotated in synchronism with the magnetic flux blocking member gear 11. To the magnetic flux blocking member gear 11, rotational force is given from a driving means 20. The driving means 20 has only to be a mechanical power source such 20 as a motor. Incidentally, the present invention is 25 not dependent upon the structure of the driving means

20. For example, the magnetic flux blocking member 3 may be rotated by a driving means comprising an actuator such as a solenoid, and a movement transmitting mechanism such as a mechanical linkage  
5 for transmitting the linear movement of the actuator to the magnetic flux blocking member gear 11 by converting the linear movement into rotational movement. Further, the magnetic flux blocking member gear 11 as the rotational force transmitting member  
10 may be replaced with a magnetic flux blocking member pulley such as the one in the third embodiment which will be described later. These modifications do not affect the effectiveness of the present invention.

The holder shaft 2b is shaped so that not  
15 only does it support the magnetic flux blocking member, but also it functions as the guide for the supply line 15 for supplying the coil 5 with electrical power. The holder supporting shaft 2b is rendered hollow, and the power supply line 15 is  
20 extended outward through the hollow of the holder supporting shaft 2b. The holder supporting shaft 2b is put through the hole 3b of the circular end of the magnetic flux blocking member 3, and the cylindrical portion of the bushing 14, being thereby rotationally supported. The outward end of the power supply line 15 is provided with a connector 15a, with which the power supply line 15 is connected to a power

controlling apparatus 25. As the unshown excitation circuit is controlled by the power controlling apparatus 25, alternating current is supplied to the coil 5 through the power supply line 15.

5       The supporting shaft 2a of the holder 2 is supported by a holder supporting plate 13, and the supporting shaft 2b of the holder 2 is supported by the holder supporting plate 17. The portion of the supporting shaft 2a, by which the supporting shaft 2a  
10      is supported by the holder supporting member 13, is D-shaped in cross section (D-cut), and is fitted in the D-shaped hole of the holder supporting member 13, fixing thereby the position of the holder 2 in terms  
15      of the circumference direction of the fixation roller 7. With the provision of the above described structural arrangement, the holder 2 is positioned so that the rotational axis 7c of the fixation roller 7 (Figure 1) coincides with the axial lines 2c of the holder supporting shaft 2a and 2b (Figure 3).

20       Referring to Figure 1, the external diameter  $\phi X$  of the magnetic flux blocking member gear 11 is smaller than the internal diameter  $\phi Y$  of the fixation roller 7, satisfying the following inequality:

25      (external diameter  $\phi X$  of the magnetic flux blocking member gear 11) < (internal diameter  $\phi Y$  of the fixation roller 7)

The above described structural arrangement

makes it possible to assemble or service (which will be described later) the heating apparatus in this embodiment from the direction of the power supply line 15 (supporting shaft 2b side of the holder) of the 5 coil 5.

Next, referring to Figures 1 and 8, an example of an assembly sequence for the fixing apparatus in this embodiment will be described.

Referring to Figure 2(a), first, the fixation 10 roller 7 is to be supported by the fixation roller supporting plates 28a and 28b, with the interposition of bearings 27a and 27b, respectively. Then, a fixation roller gear 18 is attached to one of the lengthwise ends of the fixation roller 7, that is, the 15 end fitted with the bearing 27b. Then, the same end of the fixation roller 7 is fitted with an unshown thrust control member to control the movement of the fixation roller 7 in the thrust direction. Up to this point, the assembly sequence is the same as that for a 20 fixing apparatus in accordance with the prior art.

Next, the magnetic flux adjustable heating assembly 1 is inserted into the fixation roller 7, from one end of the fixation roller 7 (bearing 27b side), from the magnetic flux blocking member gear 11 25 side, so that the other end of the magnetic flux adjustable heating assembly 1 will stick out of the other end of the fixation roller 7 (bearing 27a side).

Then, the holder supporting shaft 2a is fitted into the hole 13a of the holder supporting plate 13.

Next, the holder supporting shaft 2b (which is hollow and serves as guide for power supply line 5 15), shown in Figure 1, is fitted with the holder supporting member 17. Then, the power supply line 15 is connected to the power controlling apparatus 25; the connector 15a of the power supply line 15 is connected to the power controlling apparatus 25, 10 completing the placement of the magnetic flux adjustable heating assembly 1 into the fixation roller 7.

As described above, in the case of the fixating apparatus having the structure in this embodiment, it can be assembled without putting the power supplying line 15 directly through the fixation roller 7. Therefore, the problems that the power supply line 15 is scratched, bent, and/or stressed during the assembly of the fixing apparatus do not occur. Further, the assembly sequence for the fixing apparatus can be carried out from one end of the fixation roller 7 (fixation roller bear 18 side). Therefore, the fixing apparatus can be more efficiently assembled.

25 Next, the sequence to be carried out to disassemble the fixing apparatus in this embodiment, for example, when replacing the fixation roller 7,

magnetic flux generating means, etc., will be described.

When replacing a component of the fixing apparatus, the components of the fixing apparatus are to be removed in the order opposite to the order in which they are attached. First, referring to Figure 1, the power supply line 15 is disconnected from the power controlling apparatus 25, at one of the lengthwise ends of the fixation roller 7. Next, the holder supporting member 17 is separated from the holder supporting shaft 2b. Lastly, the magnetic flux adjustable heating assembly 1 is pulled out from within the fixation roller 7, from the holder supporting shaft 2b side, as shown in Figure 8(b), and removed.

As described above, in this embodiment, all the operations for servicing the fixing apparatus, for example, replacing a single or plurality of components thereof, can be performed from one end of the fixation roller 7. Therefore, the fixing apparatus can be more efficiently serviced compared to a fixing apparatus in accordance with the prior art. In other words, the fixing apparatus in this embodiment can be assembled or disassembled without putting, or pulling, the power supply line 15 through the fixation roller 7. Therefore, the power supply coil 5 is not scratched, bent, and/or stressed during assembling or

disassembling the fixing apparatus, in particular,  
assembling the fixing apparatus.

Also in this embodiment, the fixing apparatus  
is structured to satisfy this inequality: (external  
5 diameter  $\phi X$  of the magnetic flux blocking member gear  
11) < (internal diameter  $\phi Y$  of the fixation roller 7),  
so that the holder 2 for holding the magnetic flux  
generating means (combination of coil 5 and core 6)  
and magnetic flux blocking member 3 can be assembled  
10 into a compact unit. Therefore, the combination of  
the fixation roller 7 and magnetic flux generating  
means can be more efficiently assembled or serviced  
(their components can be replaced) compared to that in  
accordance with the prior art.

15 In the case of the fixing apparatus in this  
embodiment, the magnetic flux blocking member 3 is  
rotated in a predetermined direction by the driving  
means 20, by an angle proportional to paper (recording  
medium) size, so that the shield portions 3e and 3f,  
20 and the shield portions 3g and 3h shield the portions  
of the fixation roller 7 outside the recording medium  
track. With these shielding portions of the magnetic  
flux blocking member 3 shielding the portions of the  
fixation roller 7 outside the recording medium track,  
25 the magnetic flux is prevented from reaching the  
shielded portions of the fixation roller 7, or the  
portions outside the recording medium track, reducing

the amount by which heat is generated in the fielded portions, or the lengthwise end portions, of the fixation roller 7. Therefore, the portions of the fixation roller 7 outside the recording medium track 5 do not excessively increase in temperature.

In this embodiment, the magnetic flux blocking member 3 can be set at three positions: width A (maximum size) position at which no part of the fixation nip excessively increases in temperature; 10 width B (intermediary size) position; and width C (smallest size) position, in order to change the size of the range, in terms of the lengthwise direction of the fixation roller 7, across which heat is generated in the fixation roller 7 by electromagnetic induction. 15 For example, when recording medium (paper) width is A, B, or C, which is equivalent to A4 (297 mm), B4 (257 mm), or A4R (210 mm) width in the metric system, the distance between the pair of shielding portions of the magnetic flux blocking member 3 can be adjusted 20 according to the recording medium (paper) width by rotating the magnetic flux blocking member 3. The recording medium (paper) width (size) is determined according to the specifications of the image forming apparatus in which a fixing apparatus is mounted. The 25 number of the fixation roller shielding portions of the magnetic flux blocking member 3 does not need to be two; it can be increased or reduced depending on

the number of widths in which the recording media which will be fed to a fixing apparatus are available. It may be one, or three or more, in order to prevent the portions of the fixation nip outside the recording medium track from excessively rising.

Also in this embodiment, the fixing apparatus comprises: the coil 5; core 6; holder 2 for holding the coil 5 and core 6; magnetic flux blocking member 3. One of the lengthwise ends of the magnetic flux blocking member 3 is supported by the holder supporting shaft 2a, and the other is supported by the holder supporting shaft 2b, as described above. In other words, the holder 2 and magnetic flux blocking member 3 are integrally assembled into a compact unit.

Further, in this embodiment, the axial lines 2c (Figure 3) of the holder supporting shafts 2a and 2b by which the magnetic flux blocking member 3 is supported coincide with the rotational axis 7c (Figure 1) of the fixation roller 7. Therefore, the magnetic flux blocking member 3 can be disposed within the fixation roller 7, with the interposition of the magnetic flux blocking member gear 11 and bushing 14 fitted around the holder supporting shafts 2a and 2b, respectively, making it unnecessary to secure a space for the magnetic flux blocking member 3, on the outward side of the fixation roller 7, along the peripheral surface of the fixation roller 7.

Therefore, it is possible to reduce the size of a fixing apparatus.

Further, in this embodiment, the holder 2 for holding magnetic flux generating means (combination of coil 5 and core 6) and magnetic flux blocking member 3 are integrally assembled into a compact unit, improving not only the efficiency with which they are assembled, but also the efficiency with which the fixing apparatus can be serviced, for example, when 10 the fixation roller 7 is replaced during maintenance.

Further, the magnetic flux blocking member 3 can be rotationally driven about the rotational axis 7c of the fixation roller 7, by the driving means 20 located at one of the lengthwise ends of the fixation 15 roller 7 (supporting shaft 2a side of the holder 2). Therefore, the space for the driving means 20 has only to be provided on the supporting shaft 2a side of the holder 2, making it possible to reduce the fixing apparatus dimension in terms of the thrust direction 20 of the fixation roller 7.

Also in the case of the fixing apparatus in this embodiment, the fixation nip (heating nip) N having a predetermined width is formed between the fixation roller 7 and pressure roller 8, by placing 25 the pressure roller 3, and the fixation roller 7 internally holding the above described assembly 1 into the unshown housing of the fixing apparatus so that

the fixation roller 7 is kept vertically pressed on the pressure roller 8 from above, as shown in Figures 1 and 2.

5 The fixation roller 7 is rotated in the clockwise direction indicated by an arrow mark P by the fixation roller gear 18, causing the pressure roller 8 to be rotated in the counterclockwise direction indicated by an arrow mark Q by the rotation of the fixation roller 7.

10 The coil 5 is made to generate alternating magnetic flux, by the alternating current supplied to the coil 5 from the power controlling apparatus 25. The alternating magnetic flux is guided by the core 6 to the fixation nip N, inducing eddy current in the 15 surface portion of the fixation roller 7, in the fixation nip N. The eddy current generates Joule heat in the surface portion of the fixation roller 7 because of the resistivity of the surface portion of the fixation roller 7. In other words, as the coil 5 20 is supplied with alternating current, heat is generated by electromagnetic induction, in the fixation roller 7, in the fixation nip N.

25 The temperature in the fixation nip N is kept at a predetermined level suitable for fixation, by the temperature controlling system, inclusive of an unshown temperature sensor, which controls the alternating current supplied to the coil 5 from the

power controlling apparatus 25.

In operation, the fixation roller 7 is rotated by the rotation of the fixation roller gear 18, and alternating current is supplied to the coil 5 from the power controlling apparatus 25 to raise the temperature in the fixation nip N to the predetermined level. After the temperature of the fixation nip N reaches the predetermined level, the recording medium (paper) S bearing an unfixed toner image is inserted 10 into the fixation nip N between the fixation roller 7 and pressure roller 8, along the recording medium path H (indicated by single-dot chain line) from the direction indicated by an arrow mark C, being thereby conveyed through the fixation nip N. While the 15 recording medium S is conveyed through the fixation nip N, the recording medium S and unfixed toner image are heated by the heat generated in the fixation roller 7. As a result, the toner image is fixed to the recording medium. After being conveyed through 20 the fixation nip N, the recording medium S is separated from the peripheral surface of the fixation roller 7, on the exit side of the fixation nip N, and is conveyed further.

Next, referring to Figure 4 which is a 25 schematic sectional view of the fixing apparatus and magnetic circuit in this embodiment, the function and movement of the magnetic flux blocking member 3 of the

fixing apparatus in this embodiment will be described.

In the drawing, the magnetic flux  $J_a$  (represented by double-dot chain line) is a part of the magnetic circuit of the magnetic flux generated by the magnetic flux generating means as electric power (alternating current) is inputted into the magnetic flux generating means from the power controlling apparatus. The magnetic flux  $J_a$  passes through the primary portion 6a (perpendicular portion) of the core 6, fixation roller 7, and secondary portion 6b (horizontal portion) of the core 6. In reality, the magnetic flux passes the inward side of the fixation roller 7 higher in permeability. However, for ease of description, the line  $J_a$  is drawn as is in Figure 4.

At this time, the areas of the fixation roller 7, in which heat is generated by electromagnetic induction, will be discussed.

It is thought that in terms of the amount of heat generated in the fixation roller 7, the portions of the fixation roller 7 next to the coil 5 are the largest for the following reason. That is, magnetic flux is generated so that it shuttles through the primary and secondary portions 6a and 6b of the core 6a. Therefore, the magnetic flux density is higher in the portions of the fixation roller 7 next to the coil 5. In consideration of this concept, the magnetic flux generating means (combination of coil 5 and core

6) is slightly tilted so that heat will be generated in the portion of the fixation roller 7 in contact with the pressure roller 8, and the portion of the fixation roller 7 on the immediately upstream side of 5 the fixation nip N in terms of the rotational direction of the fixation roller 7. Further, as the fixation roller 7 is rotated, it is uniformly heated.

The magnetic flux generating means is provided to generate heat based on the principle of 10 electromagnetic induction heating. In the case of the magnetic flux adjusting means, the width of the path, through which the magnetic flux shuttles in the fixation roller, is adjusted by the magnetic flux blocking member 3 in order to control the amount by 15 which heat is generated in the lengthwise end portions of the fixation roller 7, by electromagnetic induction.

More specifically, the amount by which heat is generated in the fixation roller 7 can be 20 efficiently reduced by the placement of the magnetic flux blocking member 3 between the core 6 and fixation roller 7; if the core 6 is T-shaped in cross section, shielding the fixation roller 7 from the primary portion (perpendicular portion) 6a of the core 6 is 25 particularly effective to reduce the amount. As will be evident from the magnetic circuit Ja in Figure 4(a), the primary portion 6a of the core 6 is higher

in magnetic flux density than the secondary core 6b (horizontal portion), and the magnetic flux separates into two portions at the outward end (edge) of the portion 6a and the joint between the portions 6a and 5 6b. Therefore, it is more effective to shield the fixation roller 7 from the magnetic flux, across this portion of the magnetic circuit, that is, across the area corresponding to the outer end (edge) of the core 6a.

10 Referring to Figure 4(a), when recording medium of the width A, which does not cause any excessive temperature increase in the portions of the fixation nip N outside the recording medium track, is used, the magnetic flux blocking member 3 is kept on 15 standby in the area in which it has little effect on the magnetic circuit Ja. In Figure 4(a), the magnetic flux blocking member 3 is on standby in the area where the magnetic circuit Ja is not present. When the magnetic flux blocking member 3 is positioned as shown 20 in Figure 4(a), it does not affect the magnetic circuit Ja. Therefore, heat is generated in the fixation roller 7 by electromagnetic induction, across its entire range, which corresponds to the width A of recording medium, enabling the entirety of the 25 fixation nip N to heat the recording medium for fixation.

Referring to Figure 4(b), when recording

medium of the width  $B$ , which is capable of excessively increasing the portions of the fixation nip outside the recording medium track, the magnetic flux blocking member 3 is rotated into the position in which it  
5 interferes with the magnetic circuit  $J_a$ , preventing the magnetic flux from reaching the portion of the fixation roller 7 behind the magnetic flux blocking member 3. In Figure 4(b), the fixation roller shielding portions  $3e$  and  $3f$  of the magnetic flux  
10 blocking member 3 cover the corresponding portions of the primary portion  $6a$  of the core 6, blocking the flow of the magnetic flux flowing into, or out of, these portions of the portion  $6a$ . The magnetic circuit  $J_b$  shown in the drawing is such a magnetic  
15 circuit that is formed in the range  $B_a$  ( $B_b$ ), corresponding to the shielding portions  $3e$  ( $3f$ ) (Figure 3). As will be evident from the drawing, when recording medium of the width  $B$  is fed, the amount of the magnetic flux which passes through the fixation  
20 roller 7, in the range  $B_a$  ( $B_b$ ), corresponding to shielding portion  $3e$  ( $3f$ ), which is outside the recording medium track, is smaller compared to the amount shown in Figure 4(a). Therefore, the amount by which heat is generated by electromagnetic induction,  
25 in the portions of the fixation roller 7, corresponding to the shielding portions  $3e$  and  $3f$  having the widths of  $B_a$  and  $B_b$ , respectively, is

smaller. Therefore, the portions of the fixation nip outside the recording medium track do not excessively increase. In this case, the center portion of the fixation nip, the dimension of which, in terms of the lengthwise direction of the fixation nip, matches the recording medium width  $B$ , becomes the range in which the fixation by electromagnetic induction is possible.

When recording medium with the width  $C$ , which causes the excessive temperature increase in the

portions of the fixation nip outside the recording medium track, is used, the relationship among the recording medium width, fixation roller shielding portions of the magnetic flux blocking member 3, and range in which the fixation by electromagnetic

induction is possible, is similar to that when the recording medium is of the width  $B$ . That is, the magnetic flux blocking member 3 is further rotated into the magnetic circuit  $J_a$ . In the drawing, the shielding portion  $3g$  ( $3h$ ) of the magnetic flux

blocking member 3 is positioned between the primary portion  $6a$  of the core 6 and the fixation roller 7 to interfere with the flow of the magnetic flux. The magnetic circuits  $J_c$  and  $J_c'$  in the drawing are the results of the deformation caused by the interference from the shielding portions  $3g$  and  $3h$  having the widths of  $C_a$  and  $C_b$ , respectively (Figure 3). When recording medium with the width  $C$  is in use, the

.....

portion of the magnetic circuit, which corresponds to the portions of the fixation roller 7 shielded from the coil 5 by the shielding portions 3e and 3f with the widths Ba and Bb, and shielding portions 3g and 3h with the widths Ca and Cb, that is, the portions of the fixation roller 7 corresponding to the portions of the fixation nip outside the recording medium track, become the combination of magnetic circuits Jb, Jc and Jc' in Figures 4(b) and 4(c). In other words, the portions of the magnetic flux, which go through the fixation roller, within the above described ranges (Ba + Ca) and (Bb + Cb) are smaller than the portion of the magnetic flux which goes through the fixation roller 7 in the ranges Ba and Bb in Figure 4(a).

Therefore, the amount by which heat is generated by electromagnetic induction, in the ranges (Ba + Ca) and (Bb + Cb) is smaller, being prevented from excessively increasing the portion of the fixation nip outside the recording medium track. In this case, the center portion of the fixation nip, which corresponds to the distance 3d between the two fixation roller shielding portions of the magnetic flux blocking member 3, and the width of which equals the recording medium width C is the range in which fixation by electromagnetic induction is possible.

Embodiment 2

Next, referring to Figure 6, the second

embodiment of the present invention will be described.

The components, such as the magnetic flux generating means (5 and 6), fixation roller 7, pressure roller 8, etc., of the image forming

5 apparatus in this embodiment are the same as those in the first embodiment. The components in this embodiment which are the same in function as those in the first embodiment are given the same referential symbols as those given in the first embodiment.

10 Further, the substances used as the material for the magnetic flux blocking member 3 are the same as those used in the first embodiment.

In the second embodiment, the inequality: (external diameter  $\phi X$  of the magnetic flux blocking member gear 11) < (internal diameter  $\phi Y$  of the fixation roller 7), which is mandatory in the first embodiment, is not mandatory. In other words, this embodiment is different from the first embodiment in that the external diameter  $\phi X$  of the magnetic flux blocking member gear 11 may be greater than the internal diameter  $\phi Y$  of the fixation roller 7.

In the second embodiment, the holder supporting shaft 2a is shaped so that it can function as the guide for the power supply line 15 which supplies the coil 5 with electric power. The holder supporting shaft 2a is made hollow so that the power supply line 15 can be extended outward through the

holder supporting shaft 2a. The magnetic flux blocking member gear 11 is rotatably fitted around the holder supporting shaft 2a. Thus, the power supply line 15 can put through the magnetic flux blocking member gear 11 (holder supporting shaft 2a), and connected to the power controlling apparatus 25 with the use of the connector 15a, to supply the coil 5 with electric power.

The holder 2 is supported by the holder supporting plate 13 and the holder supporting member 17, on the supporting shaft 2a and 2b sides, respectively. The portion of the supporting shaft 2a, by which the supporting shaft 2a is supported by the holder supporting member 13, is D-shaped in cross section (D-cut), and is fitted in the D-shaped hole of the holder supporting member 13, fixing thereby the position of the holder 2 in terms of the circumference direction of the fixation roller 7.

In the second embodiment, the tip 2bT of the holder supporting shaft 2b is tapered so that the holder supporting shaft 2b can be smoothly inserted into the D-shaped hole 17a of the holder supporting plate 17 when the magnetic flux adjustable heating assembly 1 is put together. Obviously, the same effect can be obtained by tapering the tip of the holder supporting shaft 2a, in the first embodiment, through which the power supplying line 15 is put.

Next, referring to Figures 6 and 9, an example of an assembly sequence for the fixing apparatus in this embodiment will be described.

Referring to Figure 9(a), first, the fixation roller 7 is to be supported by the fixation roller supporting plates 28a and 28b, with the interposition of bearings 27a and 27b, respectively. Then, a fixation roller gear 18 is attached to one of the lengthwise ends of the fixation roller 7, that is, the end fitted with the bearing 27b. Then, the same end of the fixation roller 7 is fitted with an unshown thrust control member to control the movement of the fixation roller 7 in the thrust direction. Up to this point, the assembly sequence is the same as that for a fixing apparatus in accordance with the prior art.

Next, the magnetic flux adjustable heating assembly 1 is inserted into the fixation roller 7, from one end of the fixation roller 7 (bearing 27a side); from the tapered end 2bT side of the holder supporting shaft 2b, so that the other end of the magnetic flux adjustable heating assembly 1 will stick out of the other end of the fixation roller 7 (bearing 27b side). Then, the holder supporting shaft 2a, having the tapered tip 2bT, is fitted into the D-shaped hole 17a of the holder supporting plate 17.

Next, the holder supporting shaft 2a (which is hollow and serves as guide for power supply line

15), shown in Figure 6, is fitted with the holder supporting member 13. Then, the power supply line 15 is connected to the power controlling apparatus 25; the connector 15a of the power supply line 15 is  
5 connected to the power controlling apparatus 25, completing the magnetic flux adjustable heating assembly 1.

As described above, in the case of the fixing apparatus structured as in this embodiment, it can be  
10 assembled without putting the power supplying line 15 through the fixation roller 7. Therefore, the problems that the power supply line 15 is scratched, bent, and/or stressed during the assembly of the magnetic flux adjustable heating assembly 1 do not  
15 occur. Further, the assembly sequence for the magnetic flux adjustable heating assembly 1 can be carried out from one end of the fixation roller 7 (side opposite to fixation roller gear 18).  
Therefore, the magnetic flux adjustable heating  
20 assembly 1 can be more efficiently assembled.

In the second embodiment, there is no requirement regarding the relationship between the internal diameter  $\phi Y$  of the fixation roller 7 and the external diameter  $\phi X$  of the magnetic flux blocking member gear 11 (because the magnetic flux adjustable heating assembly 1 is inserted into the fixation roller 7 from the holder supporting shaft 2b side),

affording greater latitude in apparatus design, which is meritorious. Further, the magnetic flux adjustable heating assembly 1 is structured so that the magnetic flux blocking member gear 11 does not need to be put  
5 through the hollow of the fixation roller 7.

Therefore, the magnetic flux blocking member gear 11 is prevented from sustaining such damage as scratches and indentations.

Next, the sequence to be carried out to  
10 disassemble the fixing apparatus in this embodiment, for example, when replacing the fixation roller 7, magnetic flux generating means, etc., will be described.

When replacing the components of the fixing  
15 apparatus, they are to be removed in the order opposite to the order in which they are attached. First, the power supply line 15 shown in Figure 6 is disconnected from the power controlling apparatus 25, at one of the lengthwise ends of the fixation roller  
20 7. Next, the holder supporting member 13 is separated from the holder supporting shaft 2a. Lastly, the magnetic flux adjustable heating assembly 1 is pulled out from within the fixation roller 7, from the holder supporting shaft 2a side, as shown in Figure 9(b), and  
25 removed.

As described above, in this embodiment, all the steps for servicing the fixing apparatus, for

example, replacing a single or plurality of components thereof, can be performed from one end of the fixation roller 7. Therefore, the fixing apparatus can be more efficiently serviced compared to a fixing apparatus in accordance with the prior art. More specifically, the magnetic flux adjustable heating assembly 1 in this embodiment can be assembled or disassembled without putting, or pulling, the power supply line 15 directly through the fixation roller 7. Therefore, the power supply coil 5 is not scratched, bent, and/or stressed during assembling or disassembling the fixing apparatus, in particular, assembling the fixing apparatus.

..... Further, in the second embodiment, the magnetic flux adjustable heating assembly 1 is structured so that the power supply line 15 for the coil 5 of the magnetic flux adjustable heating assembly 1 can be put through the magnetic flux blocking member gear 11, and so that the top 2bT of the holder supporting shaft 2b, which is on the side opposite to the side where the magnetic flux blocking member gear 11 is, is tapered. In addition, the holder 2 for holding magnetic flux generating means (combination of coil 5 and core 6) and magnetic flux blocking member 3 are integrally assembled into a compact unit. Therefore, not only is the fixing apparatus in this embodiment better in the efficiency

with which the fixation roller 7, magnetic flux generating member, etc., are assembled, but also the efficiency with which the fixing apparatus can be serviced, for example, when the fixation roller 7, the 5 magnetic flux generating member, etc., are replaced.

Embodiment 3

Next, referring to Figure 7, the fixing apparatus in the third embodiment of the present invention will be described.

10 The components, such as the magnetic flux generating means (5 and 6), fixation roller 7, pressure roller 8, etc., of the image forming apparatus in this embodiment are the same as those in the first embodiment. The components in this 15 embodiment which are the same in function as those in the first embodiment are given the same referential symbols as those given in the first embodiment. Further, the substances used as the materials for the 20 magnetic flux blocking member 3 are the same as those used in the first embodiment.

In the third embodiment, in the place of the magnetic flux blocking member gear 11 in the first embodiment, a magnetic flux blocking member pulley 11 is provided, and a belt 21 is wrapped around the 25 pulley 11 and the pulley 20a of the driving means 20. Further, the third embodiment is similar to the first embodiment in that the external diameter  $\phi X$  of the

magnetic flux blocking member pulley 11 is smaller than the internal diameter  $\phi Y$  of the fixation roller 7:

5 (external diameter  $\phi X$  of the magnetic flux blocking member pulley 11) < (internal diameter  $\phi Y$  of the fixation roller 7).

Also in the third embodiment, the tip 2bT of the holder supporting shaft 2b is tapered as in the second embodiment.

10 In this embodiment, however, the size of the fixation roller 7 in terms of the circumferential direction is made greater than that in the preceding embodiments, and the magnetic flux adjustable heating assembly 1 is structured so the axial line of the  
15 fixation roller 7 does not coincide with those of the holder supporting shafts 2a and 2b, about which the magnetic flux blocking member 3 is rotated. In other words, in terms of the cross section of the magnetic flux adjustable heating assembly 1, the rotational  
20 axis of the fixation roller 7 is offset from the rotational axis 2c of the magnetic flux blocking member 3.

There are two choices of sequences for assembling the fixing apparatus, and two choices of sequences for disassembling the fixing apparatus in order to servicing the fixing apparatus, for example, replacing the components thereof. One of the assembly

or disassembly sequences makes good use of the relationship between the external diameter  $\phi X$  of the magnetic flux blocking member pulley 11 and the internal diameter  $\phi Y$  of the fixation roller 7, being therefore virtually the same as that in the first embodiment. The other of the assembly or disassembly sequences makes good use of the tapered tip 2bT of the holder supporting shaft 2b, being therefore virtually the same as that in the second embodiment. It is optional which of the two assembly or disassembly sequences is to be chosen; it may be determined based on the position of the cover of an image forming apparatus for mounting or dismounting a fixing apparatus.

The structural arrangement, in this embodiment, for the magnetic flux adjustable heating assembly 1 makes it possible for the fixation roller 7 with a larger diameter to be used with the magnetic flux adjustable heating assembly 1 for a fixation roller with a smaller diameter, making it thereby possible to make some of the components of the magnetic flux adjustable heating assembly 1 interchangeable. Therefore, the number of molds can be reduced. In other words, this structural arrangement makes it possible to reduce the cost of a fixing apparatus.

Obviously, it can be easily deduced from the

third embodiment that a plurality of magnetic flux adjustable heating assemblies 1 can be disposed in a single fixation roller with a diameter greater than that of the fixation roller 7 in this embodiment.

As described above, according to each of the above described embodiments, the fixing apparatus (magnetic flux adjustable heating assembly 1) can be assembled without putting the power supply line 15 directly through the fixation roller 7. Therefore, the problem that the power supply line 15 is scratched, bent, and/or stressed while the fixing apparatus (magnetic flux adjustable heating assembly 1) is assembled does not occur. Further, the magnetic flux adjustable heating assembly 1 can be serviced from one side of the fixation roller 7, in terms of the lengthwise direction of the fixation roller 7; for example, the components of the magnetic flux adjustable heating assembly 1 can be replaced from one side of the fixation roller 7. Therefore, the fixing apparatus can be serviced more efficiently than a fixing apparatus in accordance with the prior art. Further, with the provision of the above described structural arrangement, the fixing apparatus (magnetic flux adjustable heating assembly 1) can be assembled or disassembled without pulling or pulling the power supply line 15 through the fixation roller. Therefore, the fixing apparatus in this embodiment is

superior in assembly efficiency and component replacement efficiency to a fixing apparatus in accordance with the prior art.

Embodiment 4

5 Next, referring to Figures 10, 11, and 12, the fourth embodiment of the present invention will be described.

The fixing apparatus in this embodiment is structured so that the magnetic flux is adjustable by 10 rotating the magnetic flux generating means around the stationarily disposed magnetic flux adjusting means (magnetic flux blocking member). The components, such as the magnetic flux generating means, fixation roller, pressure roller, etc., of the image forming 15 apparatus in this embodiment are the same as those in the first embodiment. The components in this embodiment which are the same in function as those in the first embodiment are given the same referential symbols as those given in the first embodiment.

20 Further, the substances used as the materials for the magnetic flux blocking member 3 are the same as those used in the first embodiment.

The magnetic flux blocking member in this embodiment is different from that in the first 25 embodiment in that the former is formed of two components 3A and 3B (Figure 10). Referring to Figure 12, the magnetic flux blocking members 3A and 3B are

.. ..

arcuate, and have two sections distinctively different in dimensions. The shapes and dimensions of these two sections will be described later. The magnetic flux blocking members 3A and 3B are solidly attached to the 5 holder supporting plate 13 and 17, which are on the supporting shafts 2a and 2b sides of the holder 2, respectively, with the use of unshown small screws.

In the fixing apparatus in this embodiment, the holder 2 which is supporting the combination of 10 the coil 5 and core 6, as the magnetic flux generating means, is rotated about the rotational axes of the supporting shafts 2a and 2b, by the magnetic flux blocking member gear 11; the portion of the holder supporting shaft 2a, which is D-shaped in cross 15 section, is fitted in the D-shaped (D-cut) hole of the magnetic flux blocking member gear 11 so that driving force can be transmitted to the holder supporting shaft 2a. With the provision of this structural arrangement, the holder 2 can be rotated in the 20 direction indicated by an arrow mark a, or arrow mark b.

Referring to Figure 12, the magnetic flux blocking member 3A has fixation roller shielding portions (corresponding to portions of fixation nip outside recording medium track) 3p and 3r, and the 25 magnetic flux blocking member 3B has fixation roller shielding portions 3q and 3s. The shielding portions

3p and 3q are identical in shape and size, and are greater in dimension in terms of the circumferential direction of the fixation roller 7, than the shielding portions 3r and 3s which are identical in shape and size. In other words, these fixation roller shielding portions 3p (3q) and 3r (3s) correspond to the fixation roller shielding portions 3g (3h) and 3e (3f), in the first embodiment, which are different in dimension in terms of the circumferential direction of the fixation roller 7. Therefore, there is a step between the shielding portion 3p (3q) and shielding portion 3g (3h).

In other words, the fixation roller shielding portions of the magnetic flux blocking members 3A and 3B are the combination of the fixation roller shielding portions 3p and 3r, and the combination of the 3q and 3s, respectively. The portion 3p (3q) is greater in dimension in terms of the circumferential direction of the fixation roller 7 than the portion 3r (3s). In order to prevent the abnormal temperature increase in the portions of the fixation nip outside the recording medium track, by reducing the amount by which heat is generated in the portions of the fixation roller 7 outside the recording medium track in terms of the axial direction of the fixation roller 7, the holder 2 is rotated by the driving means 20, by an angle which matches the recording medium size, so

that the fixation roller shielding portions 3p and 3q, or the combination of the shielding portions 3p and 3r and the combination of the shielding portions 3q and 3s, are rotated to position the core 6a integral with  
5 the holder 2, on the opposite side of the fixation roller shielding portions 3p and 3q, or the combination of the shielding portions 3p and 3r and the combination of the shielding portions 3q and 3s, in order to shield the fixation roller 7 from the  
10 magnetic flux from the core 6a, by these shielding portions.

With the provision of the above described magnetic flux blocking members 3A and 3B, the magnetic flux can be adjusted in three widths, in terms of the  
15 axial direction of the fixation roller 7: width matching the recording medium width A (maximum size) which does not cause the excessive temperature increase in the portions of the fixation nip outside the recording medium track; width matching the  
20 recording medium width B, which is smaller than the recording medium size A; and width matching the recording medium width C, which is smaller than the recording medium width B. When recording medium size is stated in the metric system, the recording medium widths A, B, and C in the standard system are A4 (297 mm), B4 (257 mm), and A4R (210 mm). In this case, the  
25 distance between the fixation roller shielding

portions 3r and 3s and the distance between the fixation roller shielding portions 3p and 3q, in terms of the axial direction of the fixation roller 7, are adjusted so that the three ranges in terms of the lengthwise direction of the fixation roller 7, across which the fixation roller 7 is not shielded by the fixation roller shielding portions, match the three recording medium widths A, B, and C. The values of these distances are to be set in accordance with the specifications of the image forming apparatus in which the fixing apparatus is mounted. The number of the fixation roller shielding portions of the magnetic flux blocking member does not need to be limited to two. It may be increased or reduced in accordance with the number of the widths in which the recording media usable with a given image forming apparatus are available. However, when the number of the widths in which the recording media usable with a given image forming apparatus are available, and which requires the fixation roller 7 to be partially shielded is only one, the magnetic flux blocking member does not need to have two shielding portions different in size.

When the width of recording medium used in an image forming apparatus is  $\bar{A}$ , which does not cause the excessive temperature increase in the portions of the fixation nip outside the recording medium track, the relationship between the magnetic flux blocking member

3A (or 3B) and the holder 2 holding the coil 5 and core 6 is as shown in Figure 11(a). In other words, the holder 2 is positioned in the range in which the magnetic circuit Ja is not affected by the magnetic flux blocking member 3A (or 3B). When the holder 2 is in this position, magnetic flux blocking member 3A (or 3B) does not affect the magnetic circuit Ja. Therefore, the fixation by electromagnetic induction can be possible across the entire range of the fixation nip which corresponds the recording medium width A.

When the recording medium with the width B which causes the excessive temperature increases in the fixation nip outside the recording medium track, is used, the holder 2 holding the coil 5 and core 6 is rotated so that the magnetic flux blocking members are placed in the positions in which the magnetic flux blocking members block the flow of the magnetic flux. In the drawing, the fixation roller shielding portions 3p and 3q of the magnetic flux blocking members 3A and 3B are between the portion 6a of the core 6 and the fixation roller 7, blocking thereby the flow of the magnetic flux. Designated by referential symbols Jb and Jb' are the magnetic circuits when the magnetic flux is impeded by the fixation roller shielding portions 3p and 3q, by the width of Ba and Bb, respectively (Figure 12). As will be evident from the

drawing, the portions of the magnetic flux which goes through the portions of the fixation roller 7 outside the recording medium track and shielded by the fixation roller shielding portions 3p and 3q having the widths of Ba and Bb, respectively, are smaller than that those shown in Figure 11(a). Thus, the amount by which heat is generated in these portions of the fixation roller 7 by electromagnetic induction is smaller, and therefore, these portions of the fixation roller 7 do not excessively increase in temperature.

In this case, the center portion of the fixation nip, the width of which equals the recording medium width B (range between the inward edges of the fixation roller shielding portions 3p and 3q perpendicular to the axial direction of the fixation roller 7) is where the fixation by electromagnetic induction is possible.

The operation of the magnetic flux adjustable heating assembly 1 when the recording medium with the width C, which causes the excessive temperature increase in the portions of the fixation nip outside the recording medium track, is used is similar to that when the recording medium with the width B is used. That is, the holder 2 holding the coil 5 and core 6 are further rotated in order to cause the primary portion 6a of the core 6 to face the fixation roller shielding portions 3r and 3s of the magnetic flux blocking members 3A and 3B, as shown in the drawing.

so that the flow of the magnetic flux is impeded by the shielding portions 3r and 3s. The referential symbols  $J_c$  and  $J_c'$  designate the portions of the magnetic circuits from the portions of the core 6 covered by the shielding portions 3r and 3s having the widths of  $C_a$  and  $C_b$ . The referential symbols  $J_b$ ,  $J_b'$ ,  $J_c$ , and  $J_c'$  in Figures 11(b) and 11(c) designate the portions of the magnetic flux which go through the portions of the fixation roller 7 outside the track of the recording medium with the width of C and shielded from the portion 6a of the core 6 by the combination of the shielding portions 3p and 3r, having a total width of  $(B_a + C_a)$ , and the combination of 3q and 3s, having a total width of  $(B_b + C_b)$  (Figure 11). As will be evident from the drawing, the portions of the magnetic flux which go through the fixation roller shielded from the primary portion 6a of the core 6 by the combination of the shielding portions 3q and 3s, having the width of  $(B_a + C_a)$ , and the combination of the shielding portions 3p and 3r, having the width of  $(B_b + C_b)$ , is smaller than that in Figure 11(a). In other words, the amount by which heat is generated in these portions of the fixation roller 7, having the widths of  $(B_a + C_a)$  and  $(B_b + C_b)$ , respectively, by electromagnetic induction is smaller, and therefore, these portions do not excessively increase in temperature. In this case, the center portion of the

fixation nip, the width of which equals to the recording medium width C (range between the inward edges of the fixation roller shielding portions 3r and 3s perpendicular to the axial direction of the fixation roller 7) is where the fixation by electromagnetic induction is possible.

Embodiment 5

Next, referring to Figure 15, the fixing apparatus in the fifth embodiment of the present invention will be described.

The fixing apparatus in this embodiment is an example of a fixing apparatus in which the magnetic flux adjustable heating assembly 1 in the first embodiment is placed in a fixation roller 7, the radius r2 of which is twice the rotational radius r1 of the magnetic flux blocking member 3 ( $r_1 < r_2$ ). In this embodiment, the axial line of the fixation roller does not coincide with the rotational axis of the magnetic flux blocking member 3. In other words, the rotational axis o1 of the magnetic flux blocking member 3 is offset from the rotational axis of the fixation roller 7. The components, such as the magnetic flux generating means 5 and 6, pressure roller 8, etc., of the image forming apparatus in this embodiment are the same as those in the first embodiment. The components in this embodiment which are the same in function as those in the first

embodiment are given the same referential symbols as those given in the first embodiment. Further, the substances used as the materials for the holder 2 and magnetic flux blocking member 3 are the same as those  
5 used in the first embodiment.

In the case of the fixing apparatus in this embodiment, the effects similar to those obtained by the first embodiment are obtained by rotating the magnetic flux blocking member 3 in the direction  
10 indicated by an arrow mark a or b, relative to the assembly 1, within the fixation roller 7.

The structural arrangement, in this embodiment, for the magnetic flux adjustable heating assembly 1 makes it possible for the fixation roller 7 with a larger diameter to be used with the magnetic flux adjustable heating assembly 1 for a fixation roller with a smaller diameter, making it thereby possible to make some of the components of the magnetic flux adjustable heating assembly 1  
15 interchangeable. Therefore, the number of molds can be reduced. Thus, this structural arrangement makes it possible to reduce the cost of a fixing apparatus.  
20

Obviously, it can be easily deduced from the fifth embodiment that a plurality of magnetic flux adjustable heating assemblies 1 can be disposed in a single fixation roller.  
25

Embodiment 6

Next, referring to Figures 14 and 15, the sixth embodiment of the present invention will be described.

Figure 14 is a schematic sectional view of  
5 the fixing apparatus in the sixth embodiment of the  
present invention, showing the general structure  
thereof. Figure 15 is a schematic sectional view of  
the fixing apparatus in the sixth embodiment and  
magnetic circuit, depicting the functions and  
10 movements of the magnetic flux blocking member in the  
sixth embodiment.

The fixing apparatus in the sixth embodiment  
essentially comprises: a magnetic flux adjustable  
heating assembly 1, a fixation film 7, a  
15 semicylindrical film guiding member 23, and a pressure  
roller 8 as a rotational pressuring member. The  
structure of the magnetic flux adjustable heating  
assembly 1 is the same as that in the first  
embodiment, except that instead of a fixation roller  
20 7, a fixation film similar to a fixation film in  
accordance with the prior art, is employed as an  
inductive heating member.

A cylindrical (seamless) fixation film 7 as  
an inductive heat generating member, is loosely fitted  
25 around a semicylindrical film guiding member 23. The  
magnetic flux adjustable heating assembly 1 in this  
embodiment is structured so that the magnetic flux

blocking member 3 can be moved into the gap between the magnetic flux adjustable heating assembly 1 and semicylindrical film guiding member 23 as is the magnetic flux adjustable heating assembly 1 in the  
5 first embodiment is structured so that the magnetic flux blocking member 3 can be moved into the gap between the magnetic flux generating means (combination of coil 5 and core 6) and the fixation roller 7.

10       The fixation nip (heating nip) N having a predetermined width is formed between the cylindrical film guiding member 23 and pressure roller 8, by placing the magnetic flux adjustable heating assembly 1 into the unshown housing of the fixing apparatus so  
15 that the semicylindrical film guiding member 23 is kept vertically pressed on the pressure roller 8 from above. In this fixation nip N, the internal surface of the fixation film 7 is kept in contact with the downwardly facing surface of the semicylindrical film  
20 guiding member 23.

... The pressure roller 8 is rotationally driven in the direction indicated by an arrow mark B by an unshown driving means. As the pressure roller 8 is driven, the fixation film 7 is rotated by the friction between the peripheral surface of the pressure roller 8 and the external surface of the fixation film 7, in the fixation nip N. As a result, the fixation film 7

rotates in the direction indicated by an arrow mark A,  
around the semicylindrical film guiding member 23,  
with the internal surface of the fixation film 7  
sliding on the downwardly facing surface of the  
5 semicylindrical film guiding member 23.

The coil 5 is made to generate alternating magnetic flux, by the alternating current supplied to the coil 5 from an unshown excitation circuit. The alternating magnetic flux is guided by the core 6 to the fixation nip N, inducing eddy current in the electromagnetic induction heat generation layer of the fixation film 7, in the fixation nip N. The electromagnetic induction heat generation layer of the fixation film 7 will be described later. The eddy 10 current generates Joule heat in the electromagnetic induction heat generation layer of the fixation film 7 because of the resistivity of the layer. In other words, as the coil 5 is supplied with alternating current, heat is generated by electromagnetic 15 induction, in the fixation film 7, in the fixation nip N.  
20

The principle of the electromagnetic induction heating, and the method for image fixation, in this embodiment which employs the fixation film 7, 25 are the same as those in the first embodiment.

In the sixth embodiment which employs the fixation film 7, as a recording medium S passes

through the fixation nip N, the recording medium S separates from the external surface of the fixation film 7 because of the curvature of the semicylindrical film guiding member 23, on the exit side of the 5 fixation nip N. Therefore, separation claws such as those required when the fixation roller is employed are not necessary.

The semicylindrical film guiding member 23 is an electrically insulating and heat resistant member 10 which does not prevent the magnetic flux from going through the member, and guides the cylindrical fixation film 7, by the internal surface of the fixation film 7, while the fixation film 7 rotates around the semicylindrical film guiding member 23, 15 playing the role of stabilizing the rotation of the fixation film 7.

The fixation film 7 in the sixth embodiment is the same as a fixation film in accordance with the prior art. That is, it is a multilayer film 20 comprising three layers: an electromagnetic induction heat generation layer, or the most inward layer (layer on the film guiding member 23 side); an elastic layer, or the layer on the outward side of the heat generation layer; and a release layer, or the 25 outermost layer (surface layer, or layer on pressure roller S side).

The arcuate magnetic flux blocking member 3

is rotatable in the direction indicated by an arrow mark a or b, through the gap between the semicylindrical film guiding member 23 and the magnetic flux generating means (combination of coil 5 and core 6). The role of the magnetic flux blocking member 3 in this embodiment is the same as those in the other embodiments in that it prevents or minimize the excessive temperature increase in the portions of the fixation nip N outside the recording medium track, by reducing the density of the effective alternating magnetic flux in the portions of the fixation nip N outside the recording medium track, compared to that in the portion of the fixation nip N inside the recording medium track, when recording mediums, the width of which is such a width that causes the excessive temperature increase, is used.

Figure 15 is a schematic sectional view of the fixing apparatus and the effective magnetic circuit in the sixth embodiment of the present invention. The changes in the magnetic circuit caused by the magnetic flux blocking member 3, that is, the flow of the magnetic flux when the portion 6a of the core 6 is partially covered with the shielding portions of the magnetic flux blocking member 3, are the same as those in the first embodiment, and are as follows.

Figure 15(a) shown the magnetic circuit

formed when recording medium with the width A which does not cause the excessive temperature increase in the portions of the fixation nip N outside the recording medium track is used. The magnetic flux 5 blocking member 3 is on standby in the position in which it does not affect the magnetic circuit Ja. When the magnetic flux blocking member 3 is in this standby position, fixation is possible across the entirety of the fixation nip N, the dimension of the 10 effective range of which virtually matches the width A of the recording medium.

When the recording medium with the width B which causes the excessive temperature increases in the fixation nip outside the recording medium track, 15 is used, the magnetic flux blocking member 3 is rotated into the magnetic circuit, as shown in Figure 15(b), impeding the flow of the magnetic flux. Designated by referential symbol Jb in the drawing is the magnetic circuit when the magnetic flux is impeded 20 by the fixation roller shielding portions 3e and 3f, by the width of Ba and Bb, respectively (Figure 3). As will be evident from the drawing, the portions of the magnetic flux which go through the portions of the fixation roller 7 outside the recording medium track 25 and shielded by the fixation roller shielding portions 3e and 3f having the widths of Ba and Bb, respectively, are smaller than those shown in

Figure 15(a). Thus, the amount by which heat is generated in these portions of the fixation roller 7 by electromagnetic induction is smaller, and therefore, these portions of the fixation roller 7 do not excessively increase in temperature. In this case, the center portion of the fixation nip, the width of which equals the recording medium width B (range between the inward edges of the fixation roller shielding portions 3e and 3f perpendicular to the axial direction of the fixation roller 7) is where the fixation by electromagnetic induction is possible.

The operation of the magnetic flux adjustable heating assembly 1 when the recording medium with the width C, which causes the excessive temperature increase in the portions of the fixation nip outside the recording medium track, is used is similar to that when the recording medium with the width B is used. That is, the magnetic flux blocking member 3 is further rotated in order to cause the fixation roller shielding portions 3g and 3h of the magnetic flux blocking member 3 to face the primary portion 6a of the core 6, as shown in the drawing, so that the flow of the magnetic flux is impeded by the shielding portions 3g and 3h. The referential symbols Jc and Jc' designate the portions of the magnetic circuits, from the portions of the core 6 covered by the shielding portions 3r and 3s having the widths of Ca

and  $C_b$  (Figure 3). The referential symbols  $J_b$ ,  $J_b'$ ,  $J_c$ , and  $J_c'$  in Figures 4(b) and 4(c) designate the portions of the magnetic flux which go through the portions of the fixation roller 7 outside the track of the recording medium with the width of  $C$  and shielded from the portion 6a of the core 6 by the combination of the shielding portions 3e and 3g, having a total width of  $(B_a + C_a)$ , and the combination of the shielding portions 3f and 3h, having a total width of  $(B_b + C_b)$ . As will be evident from the drawing, the portions of the magnetic flux which go through the fixation roller shielded from the primary portion 6a of the core 6 by the combination of the shielding portions 3e and 3g, having the width of  $(B_a + C_a)$ , and the combination of the shielding portions 3f and 3h, having the width of  $(B_b + C_b)$ , is smaller than that in Figure 4(a). In other words, the amount by which heat is generated in these portions of the fixation roller 7, having the widths of  $(B_a + C_a)$  and  $(B_b + C_b)$ , respectively, by electromagnetic induction is smaller, and therefore, these portions do not excessively increase in temperature. In this case, the center portion of the fixation nip, the width of which equals the recording medium width  $C$  (range between the inward edges of the fixation roller shielding portions 3g and 3h perpendicular to the axial direction of the fixation roller 7) is where the fixation by

electromagnetic induction is possible.

Example of Image Forming Apparatus

The fixing apparatuses in the preceding embodiments are mounted in an electrophotographic image forming apparatus, for example. Figure 5 is a schematic sectional view of an example of an image forming apparatus equipped with the fixing apparatus 10 in the first embodiment of the present invention, showing the general structure thereof.

10       The image forming operation of the image forming apparatus 100 is as follows. An original is read by the image reading portion 106, and an electrostatic latent image is formed on the peripheral surface of the photosensitive drum 101 by exposing the peripheral surface of the photosensitive drum 101 by the image writing portion 109, based on the data obtained by reading the original, in response to a command from a controller (unshown). More specifically, prior to the exposure of the peripheral surface of the photosensitive drum 101, the peripheral surface of the photosensitive drum 101 is uniformly charged to a predetermined potential level by the charging device 102, and a beam of laser light or the like is projected by the image writing portion 109, onto the uniformly charged peripheral surface of the photosensitive drum 101 to form an electrostatic latent image on the peripheral surface of the

15

20

25

photosensitive drum 101. The latent image on the photosensitive drum 101 is developed into an image formed of toner (toner image), by the developing apparatus which employs toner. Then, the toner image 5 on the peripheral surface of the photosensitive drum 101 is conveyed by the rotation of the photosensitive drum 101 to the contact area between the peripheral surface of the photosensitive drum 101 and the transferring member of the transferring apparatus 104.

10 In synchronism with the formation and conveyance of the toner image, recording mediums S are fed one by one into the main assembly of the image forming apparatus, by the pickup roller 132, and are conveyed to the contact area between the peripheral 15 surface of the photosensitive drum 101 and the transferring member of the transferring apparatus 104. While the recording medium S is conveyed through the contact area, the toner image on the peripheral surface of the photosensitive drum 101 is transferred 20 onto the recording medium S by the transferring apparatus 104.

25 After the transfer of the toner image onto the recording medium S, the recording medium S is conveyed by the conveying apparatus to the fixation roller 7, being pinched by the fixation roller 7 and pressure roller 8 while being heated by the heat electromagnetically induced in the fixation roller by

the magnetic flux generating means disposed in the hollow of the fixation roller 7. As the result, the toner image on the recording medium S is welded to the recording medium S. Thereafter, the recording medium S bearing the fixed toner image is discharged by the pair of discharge rollers into the external delivery tray of the image forming apparatus, ending a single sequence of the image formation process.

In each of the fixing apparatuses in the preceding embodiments of the present invention, the magnetic flux generating means (combination of coil 5 and core 6) is held by the holder 2, and the magnetic flux blocking member 3 is rotated inside the hollow of the fixation roller (or film) 7, about the holder supporting portions (shafts 2a and 2b), or the lengthwise end portions of the holder 2. Therefore, the coil 5 of the magnetic flux generating means 9 does not come into contact with the magnetic flux blocking member 3, being thereby prevented from being damaged by the contact.

Further, the magnetic flux blocking member 3 is rotated about the holder supporting portions, or the lengthwise end portions of the holder. Therefore, the excessive temperature increase in the portions of the fixation nip outside the recording medium track can be prevented without affecting the fixation speed. Thus, the fixing apparatus in accordance with the

present invention is superior in image formation productivity to a fixing apparatus in accordance with the prior art.

5 In particular, in the first to sixth embodiments, the magnetic flux generating means (combination of coil 5 and core 6), holder 2, and magnetic flux blocking member 3 are assembled into an integral unit, improving the fixing apparatus in assembly efficiency and service efficiency.

10 In the first, fifth, and sixth embodiments, the rotational axis of the magnetic flux blocking member 3 is made to coincide with the rotational axis of the fixation roller 7, eliminating the need for the space in which the magnetic flux blocking member is to be kept on standby, and the space in which the means for driving the magnetic flux blocking member is to be placed. Thus, these embodiments can reduce the size of a fixing apparatus.

15 In the fourth embodiment, the rotational axis of the holder, inclusive of the magnetic flux generating means (combination of coil 5 and core 6) is made to coincide with the rotational axis of the fixation roller 7, eliminating the need for the above described standby space and driving means space.

20 Thus, the fourth embodiment can reduce the size of a fixing apparatus.

In the sixth embodiment, the magnetic flux

blocking member 3 is rotated between the fixation pressure applying member (semicylindrical film guiding member 23) and the magnetic flux adjustable heating assembly 1. Therefore, the magnetic flux blocking member 3 does not rub against the fixation film 7. Therefore, the fixation film 7 is not damaged and/or deteriorated. Further, with no contact between the magnetic flux blocking member 3 and fixation film 7, the torque necessary for driving the magnetic flux blocking member in this embodiment is smaller than that required to drive the magnetic flux blocking member of a fixing apparatus in accordance with the prior art.

As described above, the present invention makes it possible to realize an induction heating type fixing apparatus which employs a magnetic flux blocking means, and yet is smaller in size, lower in cost, lower in power consumption, and higher in productivity, than a fixing apparatus in accordance with the prior art.

#### Miscellanies

Which type of the fixing apparatus among the fixing apparatuses in the preceding embodiments of the present invention is to be selected to be mounted in a given image forming apparatus is to be determined by the specifications of the image forming apparatus.

In this specification, the present invention

is described with reference to three types of heating apparatus. However, the holder 2 in the fixing apparatus in the first or second embodiment may be positioned in the hollow of the fixation roller 7 so 5 that the axial lines of the supporting shafts 2a and 2b of the holder 2 do not coincide with the rotational axis 7c of the fixation roller 7. Such a modification does not change the effects of the present invention.

In each of the fixing apparatuses in the 10 preceding embodiments, the holder 2 holding the magnetic flux generating means and the magnetic flux blocking member 3 are assembled into a compact unit, realizing an induction heating type fixing apparatus which employs a magnetic flux adjusting means, and yet 15 is smaller in size, lower in cost, smaller in power consumption, and higher in productivity than a fixing apparatus in accordance with the prior art.

Each of the preceding embodiments was 20 described with reference to a fixing apparatus employing a fixation roller as an induction heating member. However, the employment of a fixation film, similar to a fixation film in accordance with the prior art, as an induction heating member, does not affect the effects of the present invention.

25 Further, the present invention was described with reference to a magnetic flux blocking member as a magnetic flux adjusting member. However, the heat

distribution in the fixation nip in terms of the lengthwise direction of a heating member may be changed by rotationally driving a magnetic core, instead of a magnetic flux blocking member, by a  
5 driving member.

Further, the present invention was described with reference to a magnetic flux adjusting means as a means driven by a rotational driving means. However, instead of a magnetic flux adjusting means, a means  
10 for supporting a coil may be driven by a rotational driving means. Such a modification does not affect the effects of the present invention.

The image forming method to be employed by an image forming apparatus employing the fixing apparatus  
15 in accordance with the present invention does not need to be limited to an electrophotographic image forming method. It may be an electrostatic recording method, a magnetic recording method, or the like. Further, it may be of a transfer type or a direct formation type.  
20

The usage of the heating apparatus in accordance with the present invention is not limited to the usage as an image heating apparatus such as those in the preceding embodiments. That is, the heating apparatus in accordance with the present  
25 invention also can be used as various means or apparatuses for heating an object, for example, an image heating apparatus for heating a recording medium

bearing an image, in order to improve the recording medium in the surface properties such as glossiness, an image heating apparatus for temporarily fixing an image, an heating apparatus for drying an object, a heating apparatus for lamination.

5 While the invention has been described with reference to the structures disclosed herein, it is not confined to the details set forth, and this application is intended to cover such modifications or  
10 changes as may come within the purposes of the improvements or the scope of the following claims.
